FIG. 10

Figure 1 is a plot of Attenuation (dB) versus Frequency (MHz) for a 146 MHz notch filter. The y-axis represents Attenuation (dB) from -60 to 10, and the x-axis represents Frequency (MHz) from -6 to 6. The plot shows a sharp notch at 146 MHz, with attenuation reaching approximately -55 dB. The filter has a bandwidth of 2.6 MHz, indicated by the 'Zeros at: 2 ± 1.3 MHz' label. The attenuation is approximately -15 dB at 0 MHz and -15 dB at 6 MHz.

FIG. 15

FIG. 16(a)

The diagram shows a two-stage differential signal processing circuit. The first stage consists of a differential pair of input transistors, Q65 and Q66, whose gates are connected to a common-mode feedback network (Q67, Q68) and a differential-mode feedback network (Q69, Q70). The outputs of the input transistors are connected to a differential pair of output transistors, Q71 and Q72, whose gates are connected to a common-mode feedback network (Q73, Q74) and a differential-mode feedback network (Q75, Q76). The output of the second stage is labeled RSSI.

The diagram illustrates a two-stage electronic circuit, likely a differential amplifier or a signal processing unit. The circuit is composed of two main stages, each featuring a differential amplifier structure.

Top Stage:

- Input Stage:** The top stage has two input resistors, 826 and 828, connected to a common input line. A central resistor 820 is connected to the output of the differential amplifier.
- Feedback and Biasing:** A feedback resistor 818 is connected between the output and the input. A current source 810 is connected to the output, and a load resistor 832 is connected to the input.

Bottom Stage:

- Input Stage:** The bottom stage has two input resistors, 830 and 832, connected to a common input line. A central resistor 824 is connected to the output of the differential amplifier.
- Feedback and Biasing:** A feedback resistor 822 is connected between the output and the input. A current source 814 is connected to the output, and a load resistor 838 is connected to the input.

The two stages are connected in series, with the output of the top stage feeding into the input of the bottom stage. The circuit is powered by a common supply line at the top.

FIGURE 38

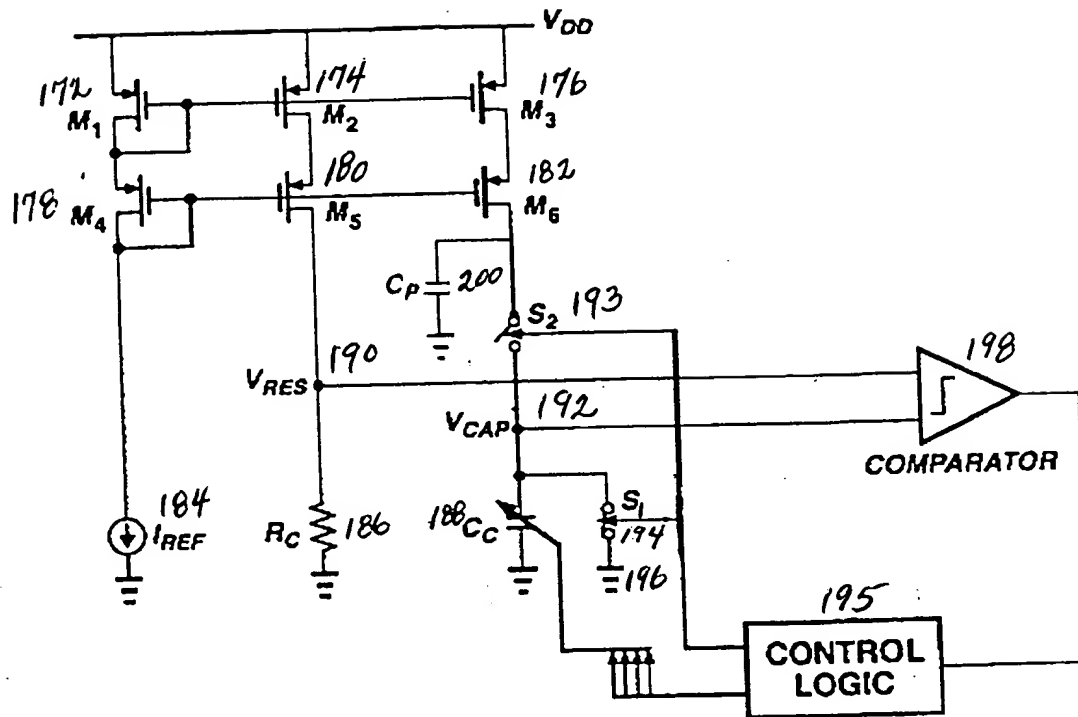

FIG. 39

FIG. 1 is a block diagram of a PLL circuit. It shows the feedback path from the VCO output back to the phase detectors. The VCO output signal is split into two paths, labeled 280 and 282. Path 280 goes to the input of the POLYPHASE A block, which outputs signal X_A . Path 282 goes to the input of the POLYPHASE B block, which outputs signal X_B . Both X_A and X_B are fed into the RSSI (Reference Signal Sampling and Interpolator) block. The RSSI block also receives a clock signal CK (250 kHz) and outputs signals $\langle C_A \rangle$ and $\langle C_B \rangle$ to the phase detectors. The RSSI block also outputs signals 284 and 286 to the CONTROL LOGIC block. The CONTROL LOGIC block outputs a signal 288 to the VCO.
